

Automated Methods For Distinguishing Copies from Original Printed Objects

Abstract of the Disclosure

This disclosure describes methods for using embedded auxiliary signals in
5 documents for copy detection and other applications. In one application, the auxiliary
signal is formed as an array of elements selected from a set of print structures with
properties that change differently in response to copy operations. These changes in
properties of the print structures that carry the embedded auxiliary signal are
automatically detectable. For example, the changes make the embedded auxiliary signal
10 more or less detectable. The extent to which the auxiliary data is detected forms a
detection metric used in combination with one or more other metrics to differentiate
copies from originals. Examples of sets of properties of the print structures that change
differently in response to copy operations include sets of colors (including different types
of inks), sets of screens or dot structures that have varying dot gain, sets of structures
15 with different aliasing effects, etc. Robust and fragile watermarks are used in Image
Replacement Documents for a variety of applications. Digital watermarks act as on-
board mediators in authentication of a variety of printed documents. Finally, digital
watermarks are used to help manage quality of the scanners used in imaging systems.
